

AMENDMENTS TO THE CLAIMS

1-2.(cancelled):

3.(previously presented): A frame synchronizing circuit comprising:
a synchronization pattern detecting unit that detects a first pattern and a second
pattern each similar to a predetermined synchronization pattern in input data within a
predetermined period of time;
a first frame synchronizing unit synchronizing with the first pattern at the first
position of the input data;
a second frame synchronizing unit synchronizing with the second pattern at the
second position of the input data;
a first error detecting unit that detects that the first position is different from the
position of the predetermined synchronization pattern, and controls the first frame synchronizing
unit to operate in accordance with the second position; and
a second error detecting unit that detects that the second position is different from
the position of the predetermined synchronization pattern,
wherein the synchronization pattern detecting unit detects a third pattern similar
to the predetermined synchronization pattern in the input frame, and controls the second frame
synchronizing unit to operate in accordance with the third position.

4.(previously presented): A frame synchronizing circuit comprising:

a synchronization pattern detecting unit that detects a first pattern and a second pattern each similar to a predetermined synchronization pattern in input data within a predetermined period of time;

a first frame synchronizing unit synchronizing with the first pattern at the first position of the input data;

a second frame synchronizing unit synchronizing with the second pattern at the second position of the input data; and

a first error detecting unit that detects that the first position is different from the position of the predetermined synchronization pattern, and controls the first frame synchronizing unit to operate in accordance with the second position,

wherein the first error detecting unit detects that the first position is different from the position of the predetermined synchronization pattern based on information other than the synchronization pattern in the frame.

5.(currently amended): A frame synchronizing circuit according to claim 4, wherein the information includes a CRC code (cyclic redundancy check), and when detecting by using the CRC code that the out-of-synchronization state of the frame continues for a predetermined period of time by using the CRC code, the first error detecting unit detects that the first position is not the position of the predetermined synchronization pattern.

6.(previously presented): A frame synchronizing circuit comprising:

a synchronization pattern detecting unit that detects a first pattern and a second pattern each similar to a predetermined synchronization pattern in input data within a predetermined period of time;

a first frame synchronizing unit synchronizing with the first pattern at the first position of the input data;

a second frame synchronizing unit synchronizing with the second pattern at the second position of the input data; and

a first error detecting unit that detects that the first position is different from the position of the predetermined synchronization pattern, and controls the first frame synchronizing unit to operate in accordance with the second position,

wherein the synchronization by the second frame synchronizing unit is selectively disabled by setting a predetermined mask.

7.(currently amended): A frame synchronizing circuit comprising:

a synchronization pattern detecting unit that detects a first pattern and a second pattern each similar to a predetermined synchronization pattern in input data within a predetermined period of time;

a first frame synchronizing unit synchronizing with the first pattern at the first position of the input data;

a second frame synchronizing unit synchronizing with the second pattern at the second position of the input data;

a first error detecting unit that detects that the first position is different from the position of the predetermined synchronization pattern, and controls the first frame synchronizing unit to operate in accordance with the second position; and

a second third error detecting unit that detects that the first position is different from the position of the predetermined synchronization pattern, based on a bit error with respect to the first pattern.

8-9. (cancelled):

10.(previously presented): A frame synchronizing circuit comprising:

a synchronization pattern detecting unit that detects a plurality of patterns similar to a predetermined synchronization pattern in the input data within a predetermined period of time;

a plurality of frame synchronizing units each synchronizing with one of the plurality of patterns specified in order of detection at the position of the input data;

a first error detecting unit that detects that a first position of the plurality of positions is different from the position of the predetermined synchronization pattern, and controls the frame synchronizing unit corresponding to the first position to operate in accordance with a second position of the plurality of positions other than the first position; and

a second error detecting unit that detects that the second position is different from the position of the predetermined synchronization pattern, and controls the frame synchronizing unit corresponding to the first position to operate in accordance with a third position of the plurality of positions other than the first position and the second position.

11.(previously presented): A frame synchronizing circuit comprising:
a synchronization pattern detecting unit that detects a plurality of patterns similar
to a predetermined synchronization pattern in the input data within a predetermined period of
time;
a plurality of frame synchronizing units each synchronizing with one of the
plurality of patterns specified in order of detection at the position of the input data; and
a first error detecting unit that detects that a first position of the plurality of
positions is different from the position of the predetermined synchronization pattern, and
controls the frame synchronizing unit corresponding to the first position to operate in accordance
with a second position of the plurality of positions other than the first position,
wherein the first error detecting unit detects that the first position is different from
the position of the predetermined synchronization pattern based on information other than the
synchronization pattern in the frame.

12.(currently amended): A frame synchronizing circuit according to claim 11, wherein
the information includes a CRC code (cyclic redundancy check), and
when detecting by using the CRC code that the out-of-synchronization of the
frame continues for a predetermined period of time by using the CRC code, the first error
detecting unit detects that the first position is not the position of the predetermined
synchronization pattern.

13.(previously presented): A frame synchronizing circuit comprising:

a synchronization pattern detecting unit that detects a plurality of patterns similar to a predetermined synchronization pattern in the input data within a predetermined period of time;

a plurality of frame synchronizing units each synchronizing with one of the plurality of patterns specified in order of detection at the position of the input data; and

a first error detecting unit that detects that a first position of the plurality of positions is different from the position of the predetermined synchronization pattern, and controls the frame synchronizing unit corresponding to the first position to operate in accordance with a second position of the plurality of positions other than the first position,

wherein the synchronization by the plurality of frame synchronizing units are selectively disabled by setting a predetermined mask.

14. (cancelled):
